(Dated: February 2, 2008)

The structure of the two-point QCD Green-functions is studied in this note in the limit of large number of colours. Their general form at next-to-leading order in $1/N_C$ is derived keeping the infinite resonance summation and without relying on a particular realization of the hadronic action. It is found that the contributions from chiral operators without resonance fields of order p^4 or higher are irrelevant for the computation of the correlators and, hence, they can be dropped at the beginning of the calculation. The possibility of a more general cancelation of these local terms at the level of the generating functional is discussed.

A large–N_C hadronic field theory

Quantum Chromodynamics (QCD) is greatly simplified in 't Hooft's large–N_C limit [1, 2, 3]. Quark loops and non-planar topologies become suppressed and the theory can be then expressed in terms of tree-level hadron exchanges. In order to produce the perturbative QCD logarithms at deep euclidian momenta, an infinite number of narrow-width states is needed.

Meson loops are absent at large–N_C and the amplitudes are analytic but for the real poles related to the narrow-width intermediate states. It is then possible to write down a lagrangian containing an infinite set of hadronic fields Φ_k of mass M_k that do not interact each other when $N_C \to \infty$. In this note, we focus our attention on the meson sector, containing the Goldstone modes from the spontaneous chiral symmetry breaking and the mesonic resonances. The main assumption in the present work is that the vertex functions $\Gamma^{(n)}_{\Phi_1...\Phi_n}$ can be described at the leading order in $1/N_C$ (LO) by a finite number of hadronic operators. These must follow the expected scaling $N_C^{1-\frac{n}{2}}$ [3], although the N_C dependence may not appear explicitly but hidden in the couplings $\lambda^{\Phi_1...\Phi_n}$ of the corresponding operators.

As result of such resonance lagrangian, loops arise at subleading orders. The N_C–scaling of the operators in the LO action $S_0^{\rm LO}[\Phi_k, J]$ converts its loop expansion [4] into an expansion in powers of $1/N_C$. The one-loop amplitudes contain ultraviolet (UV) divergences and next-to-leading order (NLO) counter-terms can be required to fulfill the renormalization.

This work studies the two-point correlators $\langle\, T\{\bar q\Gamma q(x)\ \bar q\Gamma q(0)\}\,\rangle$ or combinations of them, where $\bar q\Gamma q$ refers to some vector or axial-vector current, or to scalar or pseudo-scalar densities. These Green-functions are provided by the corresponding scalar functions $\Pi(s)$ and their short-distance behaviour can be derived through the operator product expansion (OPE) [5]. The aim of this article is to show the structure of UV divergences and counter-terms of $\Pi(s)$ at NLO in $1/N_C$. In order to avoid any model dependence, the infinite tower of states is kept all along the paper. Likewise, no explicit realization of the lagrangian is assumed, just the existence of such hadronic action.

Phenomenological large-N_C analyses have found that some $\mathcal{O}(p^4)$ chiral operators without resonance fields are absent from the hadronic lagrangian both at LO and at NLO in $1/N_C$ [6]. We will often refer along the paper to the chiral order $\mathcal{O}(p^m)$ of the operators in the way of the chiral counting, with p^m denoting the number or derivatives or external auxiliary fields v^μ, a^μ, s, p [7, 8]. This note proves that even if the presence of these chiral operators is needed to renormalize some vertex functions, they turn out to be irrelevant for the calculation of $\Pi(s)$ and do not have physical content [9]. The correlators are shown to be fully described in terms of the couplings in the LO action. A change in α_s would modify the hadronic parameters but $\Pi(s)$ would be still determined by the operators in $S_0^{\rm LO}[\Phi_k, J]$; new operators could arise at NLO but the correlator can be completely recovered even if we ignore the value of these new couplings.

The functions $\Pi(s)$ are analytical in the variable s out of the positive real s–axis and they accept general complex variable techniques [10, 11, 12, 13]. Based on the asymptotic behaviour at $|s| \to \infty$, prescribed by the OPE, one can write m–subtracted dispersion relations for $m \geq n$, where n denotes the minimal number of subtractions required for $\Pi(s)$. Other quantities with these properties are the two-meson form factors that vanish at short distances and accept unsubtracted dispersion relations [14, 15, 16]. Nevertheless, they bring further complications on other aspects and they will not be discussed here.

Moments and n–subtracted relations

For the Green-function analysis, we define a set of moments $\mathcal{A}_\Pi^{(m)}(s)$, which can be related to the spectral function for $m \geq n$ [13]:

$$\mathcal{A}_\Pi^{(m)}(s) \equiv \frac{(-s)^m}{m!}\,\frac{d^m}{ds^m}\Pi(s) = \int \frac{(-s)^m\;dt}{(t\,-\,s)^{m+1}}\;\frac{1}{\pi}\mathrm{Im}\Pi(t)\,. \tag{1}$$

The moments with $m < n$ can be derived through the recursive relation

$$\frac{\mathcal{A}_\Pi^{(m-1)}(s)}{s^{m-1}} \;=\; \frac{\mathcal{A}_\Pi^{(m-1)}(s_0)}{s_0^{m-1}} - m\int_{s_0}^{s}\frac{dt}{t^m}\,\mathcal{A}_\Pi^{(m)}(t)\,. \tag{2}$$

In order to fix $\Pi(s) = \mathcal{A}_\Pi^{(0)}(s)$ one needs to provide the value of n subtraction constants, $\{\mathcal{A}_\Pi^{(m)}(s_0)\}_{m=0}^{n-1}$ at some energy s_0.

In some cases, the OPE may prescribe $\Pi(s) \stackrel{s\to-\infty}{\longrightarrow} 0$ but the unsubtracted dispersive relation leads to an infinite resonance summation $\Pi(s) = \sum_{\Phi_k}\Pi_{\Phi_k}(s)$ that is badly defined [17, 18]. For instance, the unsubtracted dispersion relation for the SS+PP correlator is not convergent. Hence, the infinite resonance summation in $\Pi(s)_{\mathrm{SS-PP}}$ is not absolutely convergent [17]. One needs to perform a number of subtractions n higher than what is expected just from OPE arguments. Once the infinite series has been summed up in $\mathcal{A}_\Pi^{(n)}(s)$, one can use Eq. (2) to recover the lower moments $\{\mathcal{A}_\Pi^{(m)}(s)\}_{m=0}^{n-1}$. The choice $s_0 = -\infty$ gives $\mathcal{A}_\Pi^{(m)}(s_0) = 0$ for the two-point Green-functions that are chiral order-parameters [5] and fixes $\Pi(s)$.

The Green-functions that are not chiral order-parameters are more cumbersome. The subtraction constants can be obtained from the renormalized perturbative QCD correlator $\Pi(s_0)^{\mathrm{pQCD}}$ and its moments $\mathcal{A}_\Pi^{(m)}(s_0)^{\mathrm{pQCD}}$ at deep euclidian momentum $-s_0 \gg \Lambda^2_{\mathrm{QCD}}$. Furthermore, $\mathcal{A}_\Pi^{(m)}(s_0)$ is a finite and pure QCD quantity for $m \geq n$ that can be fully determined in the resonance theory. Its matching to perturbative QCD allows to recover α_s in terms of the hadronic parameters [18]. In the chiral limit, provided the value of the strong coupling constant and one renormalization condition for $\Pi(s_0)^{\mathrm{pQCD}}$ (not fixed by QCD), the rest of moments $\mathcal{A}_\Pi^{(m)}(s_0)^{\mathrm{pQCD}}$ turns out to be completely determined. This demonstrates that all the QCD information of $\Pi(s)$ is actually contained in $\mathcal{A}_\Pi^{(n)}(s)$. Moreover, this moment, determined within the resonance $1/N_C$ framework, yields the evolution from s_0 in the perturbative QCD regime down to any energy.

Before entering into the calculation of $\Pi(s)$, some more preliminary definitions are needed. Let us consider a general function $f(t)$, analytical in the whole complex plane except for logarithmic branches and single and double poles at $t = M_k^{r\;2}$. If $f(t)$ accepts a n–subtracted dispersive relation, one has the mathematical identity for its moment,

$$\begin{aligned}\mathcal{A}_f^{(n)}(s) \;&=\; \Delta\mathcal{A}_f^{(n)}(s) \\ &+\sum_k\left[\frac{(-s)^n\,Z_k^f}{(M_k^{r\;2}-t)^{n+1}} + \frac{(n+1)(-s)^n\,D_k^f}{(M_k^{r\;2}-t)^{n+2}}\right],\end{aligned} \tag{3}$$

with the coefficients

$$\begin{aligned} D_k^f \;&=\; \lim_{t\to M_k^{r\;2}} \mathrm{Re}\left\{(t-M_k^{r\;2})^2\,f(t)\right\}\,, \\ Z_k^f \;&=\; -\lim_{t\to M_k^{r\;2}} \mathrm{Re}\left\{\frac{d}{dt}\left[(t-M_k^{r\;2})^2\,f(t)\right]\right\}\,. \end{aligned} \tag{4}$$

and the absorptive contribution

$$\begin{aligned}\Delta\mathcal{A}_f^{(n)}(s) \;=\; \lim_{\epsilon\to0^+}&\left\{\frac{1}{\pi}\int_{\mathcal{R}_\epsilon}\frac{dt\;(-s)^n\;\mathrm{Im}f(t)}{(t\,-\,s)^{n+1}}\right. \\ &\left.-\frac{2}{\pi\epsilon}\sum_k\lim_{t\to M_k^{r\;2}}\frac{(-s)^n\;(t-M_k^{r\;2})^2\;\mathrm{Im}f(t)}{(t-s)^{n+1}}\right\},\end{aligned} \tag{5}$$

with $\mathcal{R}_\epsilon = [0,+\infty) - \bigcup_k(M_k^{r\;2}-\epsilon, M_k^{r\;2}+\epsilon)$. The function $\Delta\mathcal{A}_f^{(n)}(s)$ only depends on $\mathrm{Im}f(t)$ at $t \neq M_k^{r\;2}$.

For sake of clarity, the explicit derivation is shown for correlators obeying unsubtracted dispersion relations. In order to get the n–subtracted expressions, one should make the replacements,

$$\begin{aligned} \Pi(s) \;&\longrightarrow\; \mathcal{A}_\Pi^{(n)}(s)\,, \\ \frac{1}{M_k^{r\;2}-s} \;&\longrightarrow\; \frac{(-s)^n}{(M_k^{r\;2}-s)^{n+1}}\,, \\ \frac{1}{(M_k^{r\;2}-s)^2} \;&\longrightarrow\; \frac{(n+1)\,(-s)^n}{(M_k^{r\;2}-s)^{n+2}}\,, \\ \sum_{j\geq0} c_j\,s^j \;&\longrightarrow\; \sum_{j\geq n}\frac{(-1)^n\,j!}{n!(j-n)!}\,c_j\,s^j\,. \end{aligned} \tag{6}$$

Large–N_C amplitude

In the large N_C limit, the absorptive part of $\Pi(t)$ is composed by a series delta functions,

$$\frac{1}{\pi}\mathrm{Im}\Pi(t) \;=\; \sum_k Z_k\;\delta(t-M_k^2)\,, \tag{7}$$

with Z_k and M_k being, respectively, the residues and the pole positions of the QCD amplitude at large–N_C. Using dispersive relations, one gets the form of the LO amplitude,

$$\Pi(s) \;=\; \sum_k\frac{Z_k}{M_k^2\,-\,s}\,. \tag{8}$$

This amplitude can be described through the tree-level diagrams of a lagrangian with local operators containing the meson fields Φ_k of mass M_k [19]. Depending on the realization of the hadronic lagrangian, the leading action may contain $\mathcal{O}(p^2)$ resonance operators that give the resonance exchange [20],

$$\Pi(s)_{\rm res} \quad = \quad \sum_k \frac{F_k^2}{M_k^2 \, - \, s}\,. \tag{9}$$

Notice that if $\Pi(s)$ refers to the difference of two correlators, the summation may contain (-1) factors.

There may also be some local contributions of the form

$$\Pi(s)_{\rm loc} \,=\, \sum_j c_j \, s^j\,. \tag{10}$$

These operators are provided by chiral perturbation theory if we work within a chiral invariant framework [8]. Some terms only depend on the external fields, e.g., v_μ and a_μ in the case of the $\mathcal{O}(p^4)$ operator $H_1\mathcal{O}_{H_1}$ [8]. Nevertheless, there can be chiral invariant operators, like $L_{10}\mathcal{O}_{L_{10}}$ at $\mathcal{O}(p^4)$, that contain Goldstone fields in addition to the contact terms with only external sources [8]. They are non-trivial and contribute to other processes $\mathcal{M}_\Pi$ related to $\Pi(s)$ through chiral symmetry.

One may also think of further resonance operators contributing at tree-level. At LO, the only bilinear operators are the canonical kinetic term, e.g., $-\Phi_k^\dagger(\partial^2+M_k^2)\Phi_k$ for spin–0 particles. On the other hand, there can be resonance operators contributing to the $\bar{q}\,\Gamma q \to \Phi_k$ vertices with a number of derivatives higher than $\mathcal{O}(p^2)$. A term like this would give the amplitude

$$\Pi(s)_{\rm res'} \,=\, \frac{\lambda\, s^{j+1}}{M_k^2 - s}\,. \tag{11}$$

This can be always rewritten in the form

$$\Pi(s)_{\rm res'} \,=\, \frac{\lambda\,(M_k^2)^{j+1}}{M_k^2 - s} \,+\, \sum_{j'} c_{j'}^{\lambda} \;\, s^{j'}\,. \tag{12}$$

Hence, these operators reproduce the same structures found before in Eqs. (9) and (10) and do not contain further independent information. The equations of motion (EoM) provide a deeper understanding of this simplification. Every spin–0 resonance obeys a classical EoM of the form $\partial^2\Phi_k = -M_k^2\Phi_k + \chi[J,\pi] + \mathcal{O}(\Phi^2)$, where $\chi[J,\pi]$ stands for operators containing only external sources and Goldstone fields [16, 23]. The operators linear on Φ_k and contributing to $\bar{q}\Gamma q \to \Phi_k$ can be fully transformed thanks to the EoM into operators without resonance fields and terms that do not contribute to $\Pi(s)$. The case of particles with spin different from zero is more complicate due to the appearance of Lorentz structures in the EoM. Nevertheless, the study of vector fields in the antisymmetric tensor formalism casts a similar result [16, 21]. In any case, all that matters for this paper is that any tree-level contribution to $\Pi(s)$ at LO in $1/N_C$ can be written in the form of Eqs. (9) and (10), where F_k, M_k, c_j carry all the independent information. These EoM simplifications will be also crucial in the NLO analysis.

Finally, matching the QFT and the dispersive expression in Eq. (8), one gets

$$F_k^2 = Z_k\,, \qquad\qquad c_j = 0\,. \tag{13}$$

This can be better understood through the example of the vector correlator. If the spin–1 field are realized in the Proca formalism, there are no $\mathcal{O}(p^2)$ resonance operators [22]. The lowest order is $\mathcal{O}(p^3)$ and the correlator results

$$\Pi_{\rm VV}(s) \,=\, \sum_k \frac{f_{V_k}^2\, s}{M_{V_k}^2 - s} \,+\, c_0 \,+ c_1\, s \,+\, ... \tag{14}$$

It can be then recasted in the form of Eqs. (9) and (10),

$$\Pi_{\rm VV}(s) \,=\, \sum_k \frac{f_{V_k}^2\, M_{V_k}^2}{M_{V_k}^2 - s} \,+\, c_0' \,+ c_1'\, s \,+\, ... \tag{15}$$

with $c_0' = c_0 - \sum_k f_{V_k}^2$ and $c_j' = c_j$ in the rest of cases. The dispersion relation sets $c_j' = 0$ and the correlator becomes determined just in terms of M_{V_k} and $Z_k = f_{V_k}^2 M_{V_k}^2$, that contain all the physical information of $\Pi(s)$:

$$\Pi_{\rm VV}(s) \,=\, \sum_k \frac{f_{V_k}^2\, M_{V_k}^2}{M_{V_k}^2 - s}\,. \tag{16}$$

The infinite summation in the c_j' does not present a problem. To regularize it, one can always construct a series of theories with a finite number of states containing the same couplings f_{V_k}, M_{V_k} but with c_j chosen such that $c_j' = 0$. In the limit when one includes the infinite tower of resonance, such theories recover the structure of the correlator in Eq. (8) prescribed by the dispersion relations.

Amplitude at next-to-leading order in $1/N_C$

At NLO, a shift in the lagrangian parameters is required in order to absorb the one-loop UV divergences. The renormalization of the $\mathcal{O}(p^2)$ resonance couplings, $M_k^2 = M_k^{r\ 2} + \delta M_k^2$, $F_k^2 = F_k^{r\ 2} + \delta F_k^2$ gives,

$$\Pi(s)_{\rm res} \,=\, \sum_k \left[\frac{F_k^{r\ 2} + \delta F_k^2}{M_k^{r\ 2} - s} \,-\, \frac{F_k^{r\ 2}\, \delta M_k^2}{(M_k^{r\ 2} - s)^2} \right]\,. \tag{17}$$

Although the analysis of some phenomenological lagrangians have found that the corresponding local operators $c_j\mathcal{O}_{c_j}$ vanish from the action at NLO [6], we will consider the more general case when $c_j \neq 0$ and a non-zero contribution from $\Pi(s)_{\rm loc}$, given in Eq. (10), arises at NLO in $1/N_C$.

Higher $\mathcal{O}(p^m)$ operators linear in Φ_k can be removed at NLO in the same way as it was done at LO in Eqs. (11)

and (12). In addition, one may have at NLO in $1/N_C$ tree-level contributions to the resonance self-energies. A generic operator of this kind would yield the amplitude

$$\Pi(s)_{\rm res'} \;=\; \frac{\lambda\, s^{j+2}}{(M_k^{r\;2}-s)^2}\,, \tag{18}$$

where M_k^2 and $M_k^{r\;2}$ can be used indistinctly at NLO. This can be reexpressed as

$$\Pi(s)_{\rm res'} = \frac{\lambda\,(M_k^{r\;2})^{j+2}}{(M_k^{r\;2}-s)^2} - (j{+}2)\,\frac{\lambda\,(M_k^{r\;2})^{j+1}}{M_k^{r\;2}-s} + \sum_{j'} c^{\lambda}_{j'}\; s^{j'}\,, \tag{19}$$

which reproduces the momentum structures in $\Pi(s)_{\rm res}$ and $\Pi(s)_{\rm loc}$. Therefore, it does not provide any extra independent information to the correlator. Again, the study of the leading order action EoM gives a deeper understanding to this kind of simplifications [16, 21, 23]. Hence, any tree-level contribution to $\Pi(s)$ will be expressed in the form of $\Pi(s)_{\rm loc}$ and $\Pi(s)_{\rm res}$ in Eqs. (10) and (17).

The two-point Green-functions are provided at the one-loop level by the one-particle irreducible topologies (1PI) shown in Fig.(1). Hence, the perturbative expression of $\Pi(t)$ contains single an double poles at $t = M_k^{r\;2}$. The one-loop amplitude is given by the one- and two-point Feynman integrals, respectively $A_0(M^2)$ and $B_0(s, M^2, M'^2)$ [24]. Any term proportional to $A_0(M^2)$ is a rational functions of the form

$$\Pi(s)_{A_0} \;=\; \sum_j \Gamma_j^{A_0}\, s^j + \sum_k \left[\frac{Z_k^{A_0}}{M_k^{r\;2}-s} + \frac{D_k^{A_0}}{(M_k^{r\;2}-s)^2}\right] . \tag{20}$$

The contribution from a given $\Phi_1\Phi_2$ absorptive cut is provided by the $B_0(s, M_{\Phi_1}^2, M_{\Phi_2}^2)$ Feynman integral through the term

$$\Pi(s)_{\Phi_1\Phi_2} \;=\; \xi_{\Phi_1\Phi_2}(s)\,\cdot\,\mathcal{F}_{\Phi_1\Phi_2}(s)^2\,\cdot\, B_0(s, M_{\Phi_1}^2, M_{\Phi_2}^2)\,, \tag{21}$$

where $\mathcal{F}_{\Phi_1\Phi_2}(s)$ is the $\Phi_1\Phi_2$ form-factor at large–N_C and the kinematical factor $\xi_{\Phi_1\Phi_2}(s)$ is a known polynomial that depends on the channel under consideration [15, 16]. For instance, one has $\xi_{\pi\pi}(s) = \frac{2}{3}$ for the vector correlator. The form-factor, and more exactly the combination $\xi_{\Phi_1\Phi_2}(t)\,\mathcal{F}_{\Phi_1\Phi_2}(t)^2$, provides the $\Phi_1\Phi_2$ contribution to the spectral function. Hence, if the correlator follows a n–subtracted dispersion relation, also does the expression in Eq. (21). It can be then expressed through the master relation in Eq. (3),

$$\Pi(s)_{\Phi_1\Phi_2} = \Delta\Pi(s)_{\Phi_1\Phi_2} + \sum_k \left[\frac{Z_k^{\Phi_1\Phi_2}}{M_k^{r\;2}-s} + \frac{D_k^{\Phi_1\Phi_2}}{(M_k^{r\;2}-s)^2}\right] , \tag{22}$$

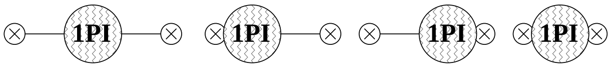

FIG. 1: 1PI contributions to the one-loop correlators.

where $\Delta\Pi(s)_{\Phi_1\Phi_2}$ is determined by ${\rm Im}\Pi(s)_{\Phi_1\Phi_2}$ at $t \neq M_k^{r\;2}$ and it is therefore free of UV–divergences. These are contained in the coefficients $Z_k^{\Phi_1\Phi_2}$, $D_k^{\Phi_1\Phi_2}$, defined as in Eq. (4). Notice that for sake of simplicity we have written down the expression for $\Pi(s)$. The transcription to higher moments $\mathcal{A}_\Pi^{(n)}$ through Eq. (6) is left to the reader. Putting the different one-loop diagrams together one gets the structure,

$$\begin{aligned}\Pi(s)_{1\ell} \;&=\; \Delta\Pi(s)_{1\ell} + \sum_j \Gamma_j^{1\ell}\, s^j \\ &\quad + \sum_k \left[\frac{Z_k^{1\ell}}{M_k^{r\;2}-s} + \frac{D_k^{1\ell}}{(M_k^{r\;2}-s)^2}\right] .\end{aligned} \tag{23}$$

Since the only two-meson absorptive contribution to the correlator comes from the one-loop amplitudes, one can write $\Delta\Pi(s)$ instead of $\Delta\Pi(s)_{1\ell}$. The summation of the Γ_j, Z_k, D_k from the different loop diagrams in $\Pi(s)_{A_0}$ and $\Pi(s)_{\Phi_1\Phi_2}$ yields, respectively, the constants $\Gamma_j^{1\ell}$, $Z_k^{1\ell}$, $D_k^{1\ell}$. Whereas the derivation of the different terms in Eq. (23) is straight-forward in the case of a QFT with a finite number of states, its definition is more cumbersome in the infinite resonance limit. This discussion is relegated for the end of the section, after the main result is obtained.

Summing up the one-loop amplitude $\Pi(s)_{1\ell}$, the local terms $\Pi(s)_{\rm loc}$ and the resonance exchanges $\Pi(s)_{\rm res}$, one gets the correlator up to NLO:

$$\begin{aligned}\Pi(s) \;&=\; \Delta\Pi(s) + \sum_j \left[c_j + \Gamma_j^{1\ell}\right] s^j \\ &\quad + \sum_k \left[\frac{Z_k}{M_k^{r\;2}-s} + \frac{D_k}{(M_k^{r\;2}-s)^2}\right] ,\end{aligned} \tag{24}$$

with

$$\begin{aligned} Z_k \;&=\; F_k^{r\;2} + \delta\, F_k^2 \,+\, Z_k^{1\ell}\,, \\ D_k \;&=\; -\,F_k^{r\;2}\,\delta M_k^2 \,+\, D_k^{1\ell}\,. \end{aligned} \tag{25}$$

The coefficients Z_k and D_k contain UV divergences from $\Pi(s)_{1\ell}$ that are canceled through the renormalizations

$$\begin{aligned} \delta F_k^2 \;&=\; -\,Z_k^{1\ell} \,+\, \Delta Z_k\,, \\ F_k^{r\;2}\,\delta M_k^2 \;&=\; D_k^{1\ell} \,-\, \Delta D_k\,, \end{aligned} \tag{26}$$

where the renormalization scheme for the couplings and masses is set by the finite constants ΔZ_k and ΔD_k, respectively. For instance, one can choose the on-shell scheme $\Delta Z_k = \Delta D_k = 0$.

Since the correlator $\Pi(s)$ obeys a n–subtracted dispersion relation (here shown unsubtracted for sake of clarity), one can apply the identity in Eq.(3):

$$\Pi(s) = \Delta\Pi(s) + \sum_k \left[\frac{Z_k}{M_k^{r\;2}-s} + \frac{D_k}{(M_k^{r\;2}-s)^2}\right] . \tag{27}$$

The comparison to the QFT calculation in Eq. (24) leads to the identities

$$\begin{aligned} F_k^{r\;2} + \Delta Z_k &= Z_k\,, \\ \Delta D_k &= D_k\,, \\ c_j + \Gamma_j^{1\ell} &= 0\,. \end{aligned} \tag{28}$$

Provided a renormalization scheme ΔZ_k, ΔD_k, the renormalized couplings F_k^r are given by the residues of the QCD amplitude at NLO in $1/N_C$. The polynomial contribution vanishes identically and it is zero for any energy, being c_j and $\Gamma_j^{1\ell}$ irrelevant for the calculation of $\Pi(s)$ (or the moment $\mathcal{A}_\Pi^{(n)}(s)$ in the case of n-subtracted dispersion relations). The analysis of the $SS-PP$ correlator in the single resonance approximation provides a practical example on the use of these techniques [15, 16].

However, the irrelevance of these local terms in other amplitudes $\mathcal{M}_\Pi$ related to $\Pi(s)$ by chiral symmetry is not so trivial. In the case when $\Gamma_j^{1\ell}=0$, the parameters c_j become zero and the local operators $\mathcal{O}_{c_j}$ disappear from the hadronic action. This situation has been found for some matrix elements within an approximation of large–N_C QCD, where only spin–0 states were included and $S_0^{\rm LO}[\Phi_k,J]$ contained operators with at most two derivatives [6]. On the other hand, a non-zero value of $\Gamma_j^{1\ell}$ induces a coupling $c_j\neq 0$ and the operators $c_j\mathcal{O}_{c_j}$ could, at first, add some analytical contribution to other chirally related amplitudes $\mathcal{M}_\Pi$.

A last important detail is whether the summation of infinite diagrams is well defined (as it happens for a theory with a finite number of states). In order to regularize this limit, it is possible to follow a procedure similar to that one employed at LO. One may consider the correlator $\Pi(s)^{\rm part.}$ provided by the partial summation of a finite number of one-loop diagrams. For every partial sum one can always keep F_k^r and M_k^r fixed and reproducing the residues Z_k and pole positions of the full QCD amplitude, and with the c_j couplings chosen such that $c_j=-\Gamma_j^{1\ell,part.}$. In the limit when one sums an infinite number of diagrams such theories lead to the Green-function prescribed by dispersion theory in Eq. (27).

Structure of the generating functional

To end with, a digression on the importance of the local terms in other amplitudes is presented. We examine the generating functional $W[J]$, given in terms of chiral invariant operators that preserve the QCD symmetries [8, 16, 23]. On what follows we will refer only to spin–0 correlators. Hadrons with higher spins complicate the argumentation since one may find that there are no $\mathcal{O}(p^2)$ resonance operators, as it happens with the spin–1 fields in the Proca formalism [22].

At leading order, $W[J]$ is provided by the LO action $S_0^{\rm LO}[\Phi_k^{cl},J]$, with Φ_k^{cl} the classical meson fields that depend implicitly on the external sources J. Actually, the LO analysis showed that the Green-functions are determined by the operators of lowest chiral order: $\mathcal{O}(p^2)$ for the scalar correlator [20], $\mathcal{O}(p^3)$ for the vector correlator in the Proca formalism [22]...

Following the derivation of the NLO amplitude in the note, the one-loop generating functional shows the structure

$$\begin{aligned} W[J] &= S_0^{\rm LO}[\Phi_k^{cl},J]+S_1^{\rm LO}[\Phi_k^{cl},J] \\ &\quad +\sum_j c_j\int dx^d\,\mathcal{O}_{c_j}[\pi^{cl},J] \;+\;[...]\,, \end{aligned} \tag{29}$$

where [...] stands for an irrelevant constant and operators that do not enter in the calculation of $\Pi(s)$ or chirally related amplitudes $\mathcal{M}_\Pi$. The term $S_1^{\rm LO}[\Phi_k^{cl},J]$ is the one-loop contribution to the generating functional coming from the integration of the quadratic fluctuations of Φ_k in the action $S_0^{\rm LO}[\Phi_k,J]$ around Φ_k^{cl} [16, 23]. The local terms $\mathcal{O}_{c_j}$ do not contain resonance fields and only depend on external sources and Goldstone fields π^{cl}.

Although we have implicitly considered n–subtracted dispersion relations all along the paper, let us suppose that the $\Pi(s)$ accept unsubtracted dispersion relations. It is then possible to write the decomposition,

$$\begin{aligned} S_1^{\rm LO}[\Phi_k^{cl},J] &= \overline{S}_1^{\rm LO}[\Phi_k^{cl},J] \\ &\quad +\sum_j \Gamma_j^{1\ell}\int dx^d\,\mathcal{O}_{c_j}[\pi^{cl},J] \;+\;[...]\,, \end{aligned} \tag{30}$$

where $\overline{S}_1^{\rm LO}[\Phi_k^{cl},J]$ generates the absorptive contribution $\Delta\Pi(s)$ and the UV divergent terms $Z_k^{1\ell}$, $D_k^{1\ell}$. These are renormalized by the $\mathcal{O}(p^2)$ resonance operators in $S_0^{\rm LO}[\Phi_k^{cl},J]$. The polynomial divergences of $\Pi(s)$ are contained in the constants $\Gamma_j^{1\ell}$. Putting the contributions $S_0^{\rm LO}[\Phi_k^{cl},J]$ and $S_1^{\rm LO}[\Phi_k^{cl},J]$ together with the $\Pi(s)$ constraint $c_j=-\Gamma_j^{1\ell}$ one gets the one-loop functional,

$$W[J] \;=\; \overline{S}_0^{\rm LO}[\Phi_k^{cl},J] \;+\; \overline{S}_1^{\rm LO}[\Phi_k^{cl},J] \;+\; [...]\,. \tag{31}$$

We have written here $\overline{S}_0^{\rm LO}[\Phi_k^{cl},J]$ since only the $\mathcal{O}(p^2)$ operators in $S_0^{\rm LO}[\Phi_k^{cl},J]$ are relevant for $\Pi(s)$ at tree-level. Hence, the replacement $W[J]\longrightarrow\overline{W}[J]$ leaves unchanged the part of the generating functional under study. This operation is understood in the sense of removing any operator in $W[J]$ of order higher than p^2 (contributing to $\Pi(s)$ or $\mathcal{M}_\Pi$). This removes the local terms $\mathcal{O}_{c_j}[\pi^{cl},J]$ that produce the polynomial contributions in correlator. The separation of the $\Gamma_j^{1\ell}$ is not arbitrary since these are the only local operators in $S_1^{\rm LO}[\Phi_k^{cl},J]$ of order p^4 or higher. This means that any local contribution c_j or $\Gamma_j^{1\ell}$ appearing in the generating functional $W[J]$, in the amplitudes $\Pi(s)$ or in related processes $\mathcal{M}_\Pi$ can be directly truncated and removed from the computation at the very beginning.

After the transformation into $\overline{W}[J]$, one reaches a functional that generates the two-point Green-functions and is renormalizable; a NLO shift of the parameters in the $\mathcal{O}(p^2)$ LO action $\overline{S}_0^{\,\mathrm{LO}}[\Phi_k^{cl},J]$ is enough to absorb the UV divergences of the one-loop contribution $\overline{S}_1^{\,\mathrm{LO}}[\Phi_k^{cl},J]$.

Although this argumentation only considers spin–0 correlators and assumes unsubtracted dispersion relations, it provides an interesting insight. The local terms $\Gamma_j^{1\ell}$, generated by the one-point Feynman integrals $A_0(M^2)$, may depend on the realization of the hadronic lagrangian [20, 25, 26]. However, this arbitrariness is not reflected in the physical amplitudes, which are uniquely determined in terms of the two-meson absorptive contributions $\mathrm{Im}\Pi(t)_{\Phi_1\Phi_2}$ and the resonance couplings F_k^r and masses M_k^r. Likewise, it is important to recall that on the contrary to what happens in momentum space, the QCD correlators are finite in configuration space and no problem of definition should arise in the large–N_C amplitudes. For instance, large–N_C QCD holographic models do not find problems on handling the infinite tower of states in the five-dimensional configuration space but the infinite summations of Kaluza-Klein modes in momentum space may eventually become ill-defined [27]. Further investigations along these lines are relegated to future works.

Conclusions

The present note demonstrates that the moments $\mathcal{A}_\Pi^{(n)}(s)$ are determined in QCD at NLO in $1/N_C$ by the operators in $S_0^{\mathrm{LO}}[\Phi_k,J]$, which give the two-meson absorptive contributions $\mathrm{Im}\Pi(t)_{\Phi_1\Phi_2}$ and the renormalized couplings F_k^r and M_k^r. These two quantities provide the residues Z_k of the QCD matrix element and the position of the poles at NLO in perturbation theory. Moreover, it is shown that the full correlator $\Pi(s)$ is actually determined by the same parameters as $\mathcal{A}_\Pi^{(n)}(s)$ together with one renormalization condition $\Pi(s_0)$ in the case of divergent QCD correlators.

In a general effective field theory, the NLO amplitude is determined by new NLO terms in the action. This analysis suggests that a large-N_C resonance QFT should not be regarded as an effective theory. In the case of two-point Green-functions, it rather resembles a "renormalizable theory" up operators $c_j\mathcal{O}_{c_j}[\pi,J]$ containing at most Goldstone fields and external sources. The local couplings c_j eventually cancel the one-loop terms $\Gamma_j^{1\ell}$ and become irrelevant for the amplitude, which can be computed even if their value remains unknown. Hence, they can be dropped from the calculation at the very beginning.

Acknowledgments

I would like to thank S. Peris, A. Pich, I. Rosell and P. Ruiz-Femenía for their criticisms and comments on the manuscript. The ideas in the present work were partially developed at IPN-Orsay and during the visit to ECT* on July 2006.
